

# Narrow paths out of poverty and educational demand: Evidence from Dominican baseball\*

Brian Marein<sup>†</sup>      Craig Palsson<sup>‡</sup>

March 26, 2024

## Abstract

Do narrow, or improbable, paths out of poverty, such as those in sports and entertainment, reduce the demand for schooling? We study the effect of professional baseball on educational attainment in the Dominican Republic, where all Major League Baseball (MLB) teams recruit teenage boys. We exploit plausibly exogenous variation in exposure to MLB's sudden entry into the Dominican Republic based on preexisting local baseball cultures and leverage the fact that girls are not recruited for baseball. Using difference-in-differences and triple-differences designs, we find that baseball has no measurable effect on school attendance, in contrast to highly publicized accounts.

# 1 Introduction

Educational investments are shaped by the returns to schooling (Adukia et al., 2020; Heath & Mobarak, 2015; Kuka et al., 2020; Oster & Steinberg, 2013). The demand for education falls as the wages of workers with low levels of education rise relative to wages of workers with high levels (Atkin, 2016; Black et al., 2005; Cascio & Narayan, 2022; Shah & Steinberg, 2017, 2021), and vice versa (Abarcar & Theoharides, 2021), although human capital accumulation in the long run may be unaffected (Emery et al., 2012). The demand for education may also be low if students or their families underestimate the returns to education, as occurs in developing countries (Jensen, 2010).

Some careers, especially in sports and entertainment, offer extremely high upside (i.e., fame and fortune) with little chance of success. For example, more than 250 million people worldwide play soccer, but only around 130 thousand do so professionally (Fédération Internationale de Football Association, 2019). In the United States, 1 in 4 members of Gen Z plan to become social media influencers (Langdon, 2022). Do such opportunities, which exert an outsized cultural influence and are thus highly visible, affect educational decisions? That is, do the slim possibilities of riches erode the perceived returns to education and reduce the demand for schooling, especially in low-income and marginalized communities where youths feel desperate to escape from poverty?

In this paper, we explore the effect of recruiting teenage boys by professional baseball teams on educational attainment in the Dominican Republic. All 30 Major League Baseball (MLB) franchises and one Japanese team operate training facilities there. In the 2022 season, 11.5% of MLB

players were born in the Dominican Republic, a country with a population of just 11 million (Baseball Almanac, 2022). Estimates of those training full time for professional baseball vary from more than 21,000 (Dominican Republic Ministry of Education, 2018) to 100,000 (Finkel et al., 2012), or about 3 to 15% of teenage boys.

We estimate the effect of baseball recruitment on the educational attainment of teenage boys in a difference-in-differences framework, exploiting the entry of MLB into the Dominican Republic following changes in its recruitment rules for domestic players and variation in preexisting local baseball cultures. Although baseball had been popular in the Dominican Republic since the early 20th century, the MLB did not extensively recruit there until the late 1970s after new MLB rules, the draft and minimum ages, reduced the benefits of signing and developing players from the United States (Bailey & Shepherd, 2011). The timing of MLB's entry into the Dominican Republic is, therefore, exogenous to Dominican boys' training and educational choices. But the recruiting shock did not affect all Dominican provinces equally. Player development depended on local baseball leagues, and American recruiters naturally looked in places that had already produced professional players. Thus, the distribution of home provinces for active players in 1977 strongly predicts the number of players that province produced from 1977 to 2010. We follow the literature (Abarcar & Theoharides, 2021; Khanna & Morales, 2017) and hypothesize that the effect of MLB's entry on educational attainment should be more pronounced in provinces that already produced professional baseball players.

Using Dominican census data and information on the birthplaces of professional ballplayers, we test whether boys of recruitment age have relatively worse educational attainment after MLB's entry into the Dominican Republic in areas that produced more players per capita prior to the establishment of MLB training academies. We find precise null results. We also compare how boys' educational outcomes change relative to girls', who are not recruited, in relation to exposure to the shock using triple-differences and find no evidence of an effect. Following Black et al. (2022) and Denes et al. (2021), we run simulated power analyses and show that our models are sufficiently powered to detect an effect for even the low-end estimates of the number of boys pursuing careers in baseball, meaning that the null results reflect a true lack of an effect rather than a lack of statistical power. We argue that baseball does not have an effect on educational outcomes, in contrast to widespread condemnation in the popular press and elsewhere, because many boys would not be in school even in the absence of baseball and/or because baseball training is overstated on the intensive (i.e., hours per week) and extensive (i.e., players pursuing professional baseball) margins. Under the latter scenario, we may not have the power to detect an effect, but the effect would not change the conclusion that such careers do not meaningfully determine educational choices and would be small enough to be unimportant from a policy perspective.

The supposed negative effect of baseball on boys' educational attainment in the Dominican Republic has been widely covered in the popular press and academic, mostly legal, journals and is the focus of an active policy discussion involving the US Agency for International Development

(USAID), the Dominican Ministry of Education, MLB, and the MLB Players Association. Wasch (2009, p. 107) shows that boys and girls enter the Dominican educational system at the same rate but that boys drop out disproportionately around the age of baseball recruitment, arguing that this pattern is circumstantial evidence that families choose baseball over school. Articles in legal journals likewise claim that MLB’s presence deters boys from attending school (Gentile, 2022; Hanlon, 2013; Kalthoff, 2013; Nieves Murphy, 2023; Ottenson, 2014; Spagnuolo, 2003; White, 2017; Williamson, 2013), as do articles published by think tanks (Council on Hemispheric Affairs, 2010; Lisman, 2019). Similar sentiments are echoed in popular outlets: VICE declares an “education crisis” (VICE Sports, 2015), and *The Nation* describes MLB recruiting as “strip-mining the Dominican Republic for talent... with no responsibility for who gets left behind” (Zirin, 2005). A director of the popular documentary *Ballplayer: Pelotero* reports meeting boys whose parents encouraged them to drop out: “[Y]ou can either go to school... or you can play baseball and maybe win the lottery” (Page-Kirby, 2012).

The only other effort to establish a causal link between MLB recruitment and educational outcomes is Chon (2020), who likewise finds no effect. The author exploits the expansion of athlete visas by the US government as an exogenous source of variation in the returns to education, comparing the years of schooling of boys of recruitment age to those too old to be recruited before and after the visa expansion, in municipalities near MLB facilities (treatment group) to those farther away (control group). The author finds similar results by classifying treatment municipalities based on the number of players born in

a municipality who appeared on minor league rosters between 2006 and 2010. The author attributes the null result to a countervailing positive effect on the returns to education caused by a spillover effect of MLB academies on local labor markets, creating jobs in local businesses such as hotels, restaurants, and private academies. That analysis, in contrast to this paper, may produce a null result because the policy change did not meaningfully impact recruiting: there is no change in the trend of Dominican players in the minor leagues after the visa expansion. The effect of MLB recruitment on education, therefore, remains an open question.

This paper contributes to the literature on the relationship between the returns to schooling and educational attainment by demonstrating that youths do not systematically pursue low-probability paths out of poverty where they would otherwise pursue education. Past work confirms theoretical predictions that the demand for education falls as the returns to education fall, but the outside employment opportunities considered in those papers are not high risk in the sense that they do not require years of up-front investment with small chances of success, unlike baseball (Adukia et al., 2020; Atkin, 2016; Black et al., 2005; Cascio & Narayan, 2022; Heath & Mobarak, 2015; Oster & Steinberg, 2013; Shah & Steinberg, 2017, 2021). In the United States, scholars have expressed concern that Black youths may see sports, rather than education, as a primary means of economic advancement (Beamon & Bell, 2006; Edwards, 2000; Gates, 1991). Black and Hispanic parents prioritize the pursuit of professional playing opportunities as an outcome for youth sports at much higher rates than do white parents (Solomon, 2020). Our study suggests

that unsatisfactory educational outcomes are caused by factors other than sports. Other studies find some evidence of a positive effect of athletics on education, but the mechanisms are skills developed rather than dropping out of school, which is less concerning in developed countries where compulsory education is enforced, unlike the Dominican Republic in past decades (Pfeifer & Cornelissen, 2010; Rees & Sabia, 2010).<sup>1</sup> In line with our findings, Ransom & Ransom (2018) finds no effect of high school sports on educational outcomes in the United States.

A closely related study, Rossi & Ruzzier (2018), exploits a European Court of Justice ruling that differentially changed opportunities to play professional soccer in Europe and finds that the increased opportunity cost of pursuing a college degree for men has a significant positive effect on the ratio of female to male tertiary enrollment in college education. Our paper is different in that we use within-country variation in exposure to the shock, and we consider effects on secondary rather than tertiary education. The most important difference, however, is that the baseball industry is far more concentrated than the soccer industry: the number of MLB players per capita in the ten most exposed Dominican provinces in 1977 is three times higher than than the number of players in the Big Five soccer leagues per capita for the ten most exposed countries in 1995, and this gap has likely grown over time. Also, of the ten most exposed countries, six are high-income and another, Uruguay, is borderline high-income. Those seven countries had a GDP per capita six times greater

---

<sup>1</sup>Eide & Ronan (2001) finds evidence that sports participation has a negative effect on the educational attainment of white males but a positive effect for black males. Harris (2014) finds no effect of sports participation on the educational attainment of black males.

than the Dominican Republic in 1990. If superstar careers have an effect on educational decisions, the effect would likely be more pronounced in the Dominican context, yet we find no effect.

This paper also contributes to the literature on the effects of foreign direct investment in developing countries. Studies generally find that FDI has important positive effects on the labor markets of host countries, including higher wages, higher productivity, and increased employment (Hale & Xu, 2016). MLB's entry into the Dominican Republic likely had large positive effects on local development, although no study has yet tried to measure the size of the impact (Meyer & Kuhn, 2008). Most concerns, however, have been about labor standards in the training academies and the effect on educational attainment. The results of this paper do not undermine the importance of MLB's educational initiatives but do suggest that those calling for reform might focus their efforts on other issues with the academies.

## **2 Baseball in the Dominican Republic**

### **2.1 Pre-MLB local baseball cultures**

Baseball was introduced to the Dominican Republic from neighboring Cuba in the late 19th century and took root in the capital, Santo Domingo, with encouragement from wealthy students exposed to the sport while attending school in the United States.<sup>2</sup> Baseball fields soon appeared throughout Santo Domingo as the sport became popular among the working class. Baseball then

---

<sup>2</sup>This subsection is based on Klein (1991, 2014) and Ruck (1998).

quickly diffused outside the capital by way of sugar production.

Sugar refineries, mostly US-owned, sponsored baseball as a diversion for cane cutters during the months they were idle from the fields. The Dominican sugar industry enjoyed explosive growth in the early 20th century, and planters filled labor needs by importing thousands of workers, mostly from Haiti and the British West Indies. Large concentrations of idle working-age men allowed teams to play organized baseball games and tournaments. Fierce rivalries developed between refineries, as tight-knit communities surrounding refineries identified with and supported their local teams. The sugar industry existed almost exclusively on the southern coast, with the highest concentration of mills in the southeast near San Pedro de Macorís. The uneven diffusion of baseball, starting in Santo Domingo before spreading via sugar estates clustered on the southern coast, generated variation in local baseball cultures over space that predates exposure to MLB investment and recruiting.

## **2.2 MLB's entry into the Dominican Republic**

Before 1965, MLB teams devoted substantial resources to identifying talented American ballplayers in their mid-teens and training them for several years in hopes of signing them once they turned eighteen.<sup>3</sup> By the late 1950s and early 1960s, however, teams felt that this system of labor recruitment cut into profits: competition over prospects led to the payment of large bonuses to rookies, and ball clubs in big cities had the resources to sign the best players, leading to competitive imbalance and, therefore, lower attendance at games.

---

<sup>3</sup>This subsection is based on Bailey & Shepherd (2011).

In 1965, the league introduced a draft and stricter age minimums to promote competitive balance and eliminate excessive bonuses. Rather than directly signing with a team, prospects entered a draft in which teams would take turns picking players in reverse order of their records from the previous season. The draft involved many rounds, with each team having the opportunity to select a player in each round. The team that drafted a player had exclusive rights to negotiate with and sign him to a contract. Players were not eligible for the draft until graduating high school, continuing a rule prohibiting teams from signing players before age eighteen. Players who went to college were not eligible for the draft until completing their sophomore year and reaching age twenty-one.

The new rules were written with American ballplayers in mind since Americans filled most MLB roster spots. Those from outside the United States were exempted because their eligibility would be difficult to verify, and many of them were already under contract to clubs in their home countries. These changes inadvertently created powerful incentives to focus on the development and recruitment of foreign players. The draft reduced the probability that a team would sign a domestic player that it scouted and developed, and the stricter age minimums reduced the incentive to invest in developing young talent since other teams would likely see players' performance by the time they became eligible to be signed. In sum, the rules reduced the expected return on investment in domestic ballplayers.

Relocating scouting activities abroad occurred slowly, as teams were unaccustomed to recruiting outside the United States. In the 1970s, teams

increasingly evaded the draft by moving their scouts to Latin America—or, more precisely, the circum-Caribbean—where baseball was popular. Cuba had been by far MLB’s most important source of foreign players but was left out of this new wave of recruitment due to the US embargo. Puerto Rico, a US territory, was heavily targeted by scouts until Puerto Ricans were subjected to the draft in 1989. The two other loci of recruitment were Venezuela and the Dominican Republic, where MLB teams opened academies to develop local players. In 1977, the Toronto Blue Jays opened the first academy in the Dominican Republic. By 1990, thirteen teams had academies in the Dominican Republic, and by 2003, all 30 MLB franchises maintained academies there. In 1985, MiLB founded the Dominican Summer League, the first affiliated league outside of the United States and Canada.

## **2.3 Dominicans in American professional baseball**

The number of Dominicans playing American professional baseball closely tracks MLB’s entry into the Dominican Republic (see Figure 1).<sup>4</sup> The first Dominican in the minor leagues debuted in 1925, and the first Dominican in the majors debuted in 1956, although he was a US citizen who attended high school in New York.<sup>5</sup> Most Dominicans were effectively barred from American baseball until the first Black player was signed by a major league team in 1947

---

<sup>4</sup>We refer to MLB and affiliated leagues as American professional baseball for simplicity despite some teams in Canada because the leagues are based in, and predominately operate in, the United States. The major leagues existed for nearly a century before expanding into Canada.

<sup>5</sup>Major League Baseball consists of the National League and American League, often called the major leagues or majors. Minor League Baseball serves as a developmental system for MLB and is often referred to as the minor leagues or minors.

(Kurlansky, 2010). Few Dominicans played professionally in North America before the 1970s. From the late 1970s, the number of Dominicans entering American professional baseball grew steadily. By the 2000s, around one in ten MLB players and one in four MiLB players hailed from the Dominican Republic (Cary, 2007).

From the beginning, the epicenter of Dominican baseball has been San Pedro de Macorís, which produces by far the most MLB players per capita of any city in the world (Florida, 2019). In 1977, the number of players in American professional baseball per capita from San Pedro was three times higher than any other province and nine times the national average; San Pedro represented just three percent of the population but 26 percent of the professional ballplayers. Between 1977 and 2010, 15 percent of new Dominican professional ballplayers came from San Pedro. According to Ruck (1998, p. xi), “[I]f the Dominican Republic has become the epicenter of Caribbean baseball, San Pedro de Macoris is its Mecca.”

The other hotbeds of talent are primarily on the southern coast. La Romana, which borders San Pedro de Macorís, had the second highest rate of player production in 1977 and is third for the period 1977 to 2010. Two other neighboring provinces, Hato Mayor (sixth from 1977-2010) and El Seibo (eighth) are also among the top producers of talent per capita. Santo Domingo—including the Distrito Nacional, which split off in 2001—produced the largest share of players (30 percent) but ranks ninth in per capita terms. The only exception to this geographical pattern is Monte Cristi (third in 1977,

fourth since) on the northern coast bordering Haiti.<sup>6</sup>

## 2.4 Baseball training and MLB recruiting

Dominican boys learn and play baseball informally from an early age.<sup>7</sup> Around age thirteen or fourteen, though sometimes younger, the most talented players are identified by and contract with *buscones*, or independent trainers, who provide daily instruction in baseball skills.<sup>8</sup> Players can first legally sign a professional contract with a ball club at sixteen and a half years old, but *buscones* tend to continue developing players until they are signed, sometimes at ages seventeen or eighteen. Players then reside and train daily at their respective MLB team's Dominican academy for up to three years.<sup>9</sup> Successful recruits move on to minor leagues in the United States.

Most training is unregulated, so it is difficult to know precisely the size of the market. Estimates of those training full time for professional baseball vary widely, from 21,000 (Dominican Republic Ministry of Education, 2018) to more than 100,000 (Finkel et al., 2012), or about 3 to 15 percent of boys ages 12 to 18. The Dominican Ministry of Education, which provides the low-end estimate of full-time trainees, estimates that there are 1,400 independent training academies in operation. According to ENTRENA et al. (2022), 97% of prospects never sign a contract with an MLB team.

---

<sup>6</sup>Santiago, the second largest city, is in the north and is tied for fourth for total number of professional players but ranks 18th per capita.

<sup>7</sup>This subsection is based on Klein (2014).

<sup>8</sup>*Buscones* also provide food and housing, secure tryouts, and assist in negotiations with professional clubs. In return, *buscones* receive a percentage of their pupils' signing bonuses.

<sup>9</sup>Players also receive language and cultural instruction and play in the Dominican Summer League, a branch of affiliated Minor League Baseball.

## 2.5 Baseball and the (perceived) returns to education

The extremely low odds of making it to the Major Leagues should not significantly impact the returns to education for Dominican boys. According to ENTRENA et al. (2022), only 3% of prospects ever sign a contract with a professional team, and of those only 2% make it to the MLB—that is, about 0.06% of prospects eventually play in the MLB. Still, the perceived returns to education may be shaped by baseball, since young prospects overestimate their chances of success and because MLB salaries are very high. In 1990, the minimum salary in the MLB was \$100,000, and the average was \$597,537 (Edmonds, 2018). By comparison, the Dominican GDP per capita was around \$2,000 in 1990. Minor league salary data are not as widely available, but the existing information makes clear that the minor leagues do not offer much upside: before the first collective bargaining agreement in 2023, MiLB salaries ranged from \$4,800 in rookie leagues to \$17,500 in AAA. Typical signing bonuses for Dominicans in the early 2000s were between \$5,000 and \$8,000 (Meyer & Kuhn, 2008). GDP per capita in the Dominican Republic today is around \$8,500. Jensen (2010) estimates that the mean earnings of Dominicans who complete secondary school are over 40% greater than those of workers who only complete primary school. In sum, most boys are better off staying in school given the infinitesimal chances of making it to the MLB and the small payoff from making it to the minor leagues, which is also unlikely. Large numbers of boys should be drawn out of school to train for baseball only if baseball affects the *perceived* returns to education.

### 3 Census and baseball data

We use data from Dominican national censuses for 1981 (8.5% sample), 2002 (10%), and 2010 (10%) from IPUMS International (Minnesota Population Center, 2020). The data include demographic information (i.e., birth year, sex, province of birth, and province of residence) and educational outcomes (i.e., attendance and years of schooling). The 1981 census was conducted just after MLB's entry, when MLB's presence was still limited and only a couple teams operated training facilities; the 2002 and 2010 censuses were conducted when MLB's activities were extensive. The 2010 census includes both individuals who were teenagers before and those who were teenagers after MLB's entry.

Data on the birthplaces of Dominicans who played in the MLB or MiLB by 2010 come from The Baseball Cube, an online aggregator of baseball-related data. The website includes information on all major leaguers since 1871 and all minor leaguers in affiliated leagues since 1977. Few Dominicans played professionally in the United States prior to 1977, so the data include the vast majority of Dominican professional ballplayers.

The level of analysis is the province, of which there are 31 plus the national district. A lower level of analysis is not possible given significant changes over time in municipal borders and imprecise reporting of births in the baseball data. We combine the *Distrito Nacional* with the province of Santo Domingo, which split in 2001, since both jurisdictions may be referred to as Santo Domingo in players' reported births, giving us 31 units of analysis. Four provinces have been founded since 1982; where possible, including in our main analysis using only the 2010 census, we use modern administrative divisions.

For all regressions, we collapse individual-level data to the provincial level.

## 4 MLB’s entry and educational outcomes

### 4.1 Educational outcomes across birth cohorts in the 2010 census

The first test of whether teenage boys’ educational outcomes respond to MLB’s entry into the Dominican Republic uses only the 2010 census and is based on the following regression:

$$Education_{pt} = \sum_{t \neq 1959-62} \gamma_t Pre-MLB_p \cdot \delta_t + \theta_p + \delta_t + \varepsilon_{pt} \quad (1)$$

where  $Education_{pt}$  is an educational outcome (i.e., years of schooling or completion (0/1)) for boys born in province  $p$  in year  $t$ .  $\theta_p$  are province fixed effects to control for any time-invariant factors at the province level that are correlated with education, and  $\delta_t$  are birth year fixed effects to control for any factors that are common across all provinces but change over time and are correlated with education. To ensure sufficiently large cohort sizes, four years of births are grouped together. The reference cohort consists of males born between 1959 and 1962, since boys born immediately thereafter were the first to be of primary school (grades 1-8) age with MLB academies in operation. Men born before 1951 are excluded because there are too few observations per birth cohort, as are men born after 1990 to keep groups of four years and because many are too young to be expected to finish secondary school. Girls

are excluded because they are not recruited for professional baseball.

The variable of interest is  $Pre-MLB_p$ , which is the total number of active players in the MLB or MiLB in 1977 who were born in province  $p$  divided by the population of  $p$  in 1981.<sup>10</sup> The variable is intended to measure local baseball cultures as they existed just prior to MLB’s entry. It is similar to the logic of a shift-share instrument—the distribution of provinces producing players before the policy change should predict where players come from after the policy shifts demand—and is the established way to measure the effect of migration policy changes that affect a single occupation (Abarcar & Theoharides, 2021; Khanna & Morales, 2017). The year 1977 is chosen for this variable in part because it is the first year for which MiLB data are available from The Baseball Cube. But 1977 is also the year that the first MLB academy opened in the Dominican Republic, such that the distribution of ballplayers across provinces is unrelated to location-specific MLB investment. Our measure of exposure to the shock should not be affected by endogenous responses to MLB recruitment. The variable is interacted with birth cohort fixed effects since it does not change over time, revealing how educational outcomes change in more exposed communities over time.

In any case, the distribution of birthplaces of Dominicans in American professional baseball has remained stable since MLB’s entry into the Dominican Republic, as seen in Figure 3. The provinces from which players

---

<sup>10</sup>As previously noted, several provinces were formed between 1982 and 2001 by splitting off of other provinces, but we use modern provincial definitions. To estimate population in 1981 for provinces which did not yet exist, we reassign some of a “mother” province’s 1981 population to the new province, with the share based on the relative populations of the “mother” and new provinces in 2002.

tended to come before MLB's entry are the provinces from which players came after MLB's entry: the Pearson correlation coefficient for the per capita number of active players in 1977 and the per capita number of player debuting from 1977 to 2010 is 0.84. Even when San Pedro de Macorís is excluded, the coefficient is 0.67. The only visible exception is Peravia, which in 1977 had produced the sixth highest number of professionals per capita but which has emerged as the second top producer since then. When Peravia is excluded, the correlation coefficient is 0.94.

The first difference in this difference-in-differences design is based on time or, more precisely, birth year: earlier cohorts did not encounter MLB investment and recruiting, whereas later cohorts were exposed. Although some Dominicans did play professionally in North America prior to MLB's entry, the numbers were small. There were 90 Dominicans active in American professional baseball in 1977, compared to 1,078 in 2009.<sup>11</sup> Initially, MLB teams did not engage in player development and skimmed only those payers who were impossible to ignore (Klein, 2014). It is safe to assume that young Dominicans were not thinking about baseball as a career path until American scouts regularly showed up.

The second difference is based on exposure to MLB's entry across space. The production of baseball talent is not uniform across Dominican provinces. We assume that the areas that are most affected by MLB's entry are those with a strong preexisting baseball culture. Although we do not observe MLB investment directly, we know that the hotbeds of talent in 1977 have continued

---

<sup>11</sup>We use 2009, instead of 2010, here and in the appendix to exclude players in the Dominican Summer League, who are included in The Baseball Cube data from 2010 forward.

to be so during the build up of MLB activities in the decades thereafter. We are agnostic about the mechanisms—e.g., better competition, better training, more role models, access to scouts, etc.—through which a local community influences baseball outcomes and, instead, simply assume that a boy born in a community with a strong baseball culture sees greater opportunities to reach American professional baseball than does one in a community with a comparatively weak baseball culture. A boy growing up in San Pedro de Macorís—“that town with all the shortstops” (Kurlansky, 2010, p. 97)—must see baseball more optimistically than a boy in Baoruco, Independencia, or Pedernales—provinces which have produced no major leaguers.<sup>12</sup>

By taking the difference in differences, we test whether educational outcomes change differentially in communities more exposed to MLB’s entry than in communities less affected. More precisely, we want to know whether educational outcomes in provinces more exposed to the shock worsen relative to less exposed provinces after MLB enters the Dominican Republic, as would be expected if the negative accounts of professional baseball’s effect on education are true. In other words, educational outcomes would become relatively worse in provinces which produce more ballplayers per capita. The exact timing of the decline is somewhat fuzzy because MLB’s entry was not sharp, but, based on Figure 1, the effect should emerge around the time that MLB gains a foothold in the Dominican Republic with the establishment of the first academy in 1977 and increase in magnitude thereafter as investment ramps up. The identifying assumption is parallel trends, or that educational outcomes in

---

<sup>12</sup>Shortstop is one of the most important of the nine defensive positions in baseball.

more exposed communities would have changed by the same amount as less exposed communities if MLB had not come to the country. Although the assumption cannot be tested, flexible estimation reveals whether educational outcomes were changing differentially with respect to local baseball cultures prior to MLB's entry, which informs the assumption.

Figure 4 displays the results for Equation 1. One coefficient for a pre-treatment period is statistically significant at the 10% level with primary school (grades 1-8) completion and years of schooling, respectively, as the dependent variable; no pre-treatment period is statistically different from zero with high school completion as the dependent variable.  $F$ -tests for joint significance of pre-1959 coefficients produce  $p$ -values of 0.19, 0.53, and 0.20, respectively, for the three outcomes, such that the null hypothesis of no significant pre-trends cannot be rejected at conventional levels. The absence of significant pre-trends gives reason to believe that the parallel trends assumption holds after 1965.<sup>13</sup>

There is no clear jump or downward trend after the reference cohort, 1959-62, or at any point thereafter, for any of the three outcomes. To summarize the effect of MLB on boys' education, taking a linear combination of the coefficient estimates for post-treatment period suggests that a one standard deviation increase in pre-MLB baseball culture results in a decrease of 0.1 percentage points [95% CI: -1.3, 1.1] in the probability of completing high school and 0.04 fewer years of schooling [95% CI: -0.15, 0.14]. The estimated

---

<sup>13</sup>Note that, although a pre-treatment coefficient is marginally significant for two of the outcomes, the reference year outcome is low relative to subsequent periods. For example, the relevant pre-treatment period is statistically indistinguishable from the period 1963-66 for both outcomes ( $p=0.20$  and  $p=0.21$ , respectively).

effect on completing primary school is slightly positive (0.7 percentage points [95% CI: -0.7, 2.0]). All coefficient estimates are small and none are statistically distinguishable from zero. Coefficients are not even consistently negative. Confidence intervals are economically small. Primary school completion is the most appropriate outcome to measure since students begin training around age 12, and we can rule out effects larger than a decrease of 0.7 percentage points in the probability of completing primary school based on the 95% confidence interval. In other words, we find precise null results. The results are robust to using the number of baseball players from 1977 to 2010 per capita as an alternative measure of exposure (see Appendix Figure A1). If professional baseball had a large negative effect on education, boys in communities more exposed to the shock would have relatively worse educational outcomes after MLB's entry; they do not, suggesting no such effect.

The coefficient estimates are difficult to interpret because the number of boys pursuing careers in baseball is imprecise and, at the provincial level, unknown. Nonetheless, a back-of-the-envelope calculation can improve understanding. The low-end estimate of athletes pursuing professional baseball is 21,000, which translates to 2.7 percent of all teenage boys. From 1978 to 2009, 15 percent of Dominicans in American baseball came from San Pedro de Macorís, while the province constituted 3.2 percent of the national population—that is, San Pedro produced nearly five times more ballplayers than would be expected given its population. A fair assumption is that San Pedro also produced 15 percent of boys training for professional baseball, which implies that about 13 percent of boys in San Pedro train for baseball. With an

average effect of 0.11 fewer years of schooling for all boys in San Pedro relative to the least exposed communities in the last five treatment periods—that is, birth years in which the point estimate is negative—a boy in San Pedro pursuing professional baseball would end up with less than one fewer year of schooling on average. This estimate should be interpreted as an upper-bound, based on intentionally conservative assumptions, with the evidence suggesting no significant difference.

It is important to consider statistical power in the context of a null result, as the true effect may be too small to be reliably detected by the model. But power is difficult to estimate for complex econometric models, such as Equation 1 where treatment is continuous and occurs repeatedly over many years. To rule out that the null result reflects a lack of statistical power, we follow Black et al. (2022) in running simulated power analyses. Specifically, we run simulations using the same number of provinces and years of data but only include females, who are assumed to be untreated, to ensure all underlying data are untreated. In each simulation, we randomly re-assign  $Pre-MLB_p$  to provinces, ensuring that the variation in treatment does not differ from the actual data, which could lead to overestimation of power. We then impose treatment effects of varying sizes based on the randomly assigned treatment and calculate the percentage of simulations that detect a negative effect at the 5% and 10% levels. Based on these results, we report the minimum detectable effect (MDE), or the smallest effect size that is rejected in 80% and 50% of simulations, respectively.<sup>14</sup>

---

<sup>14</sup>For example, Shapiro et al. (2021) assess statistical power at the 50% threshold.

For the main outcome variable, primary school completion, we can detect effects of 2.0 and 2.2 percentage points per standard deviation increase in exposure to MLB at the 5 and 10% levels, respectively, with 80% power and effects of 1.4 and 1.2 percentage points with 50% power (see Figure A3). Put another way, going from the least to the most exposed communities—from a community with no active professional players in 1977 to San Pedro de Macorís—we can detect effects of 11.5 and 10.5 percentage points at the 5 and 10% levels, respectively, with 80% power and effects of 7.5 and 6.5 percentage points with 50% power. Under the most conservative estimate of the number of boys training for professional baseball—(more than) 21,000 between the ages of 12 and 19, or roughly 2.7% of that age range—about 13% of boys in San Pedro de Macorís train for baseball, compared to less than 1% in the least affected communities.<sup>15</sup> The model is sufficiently powered to rule out such effects under the assumption that all those boys would otherwise be enrolled in school and reasonably well powered to rule out that only half of them would otherwise be in school—once again, under the most conservative assumptions. Following Denes et al. (2021), we also validate our model by confirming that the average estimated effect in the simulations is approximately equal to the imposed effect (see Figure A4).

## 4.2 School attendance across censuses, 1981-2010

The second test of whether teenage boys' educational outcomes respond to MLB's entry uses the 1981, 2002, and 2010 censuses and is based on the

---

<sup>15</sup>A denominator that includes all boys ages 12 to 19 is conservative because most boys training for professional baseball are younger than 19, or even 17.

following regression:

$$Attendance_{apt} = \sum_{t>1981} \gamma_t Pre-MLB_p \cdot \delta_t + \theta_p + \mu_a \cdot \delta_t + \varepsilon_{apt} \quad (2)$$

where  $Attendance_{apt}$  is average school attendance for age  $a$  in province  $p$  in census year  $t$ . In this model,  $\delta_t$  are census year fixed effects to control for any factors that are common across all provinces but change over time and are correlated with education. Age-specific census year fixed effects control for age-specific changes in attendance common across the country over time. The reference year is 1981. Although 1981 falls after the first MLB academy opened in 1977, only two teams had academies then, and the academies were small compared to their modern form. The first fully modern academy opened in 1986, and MLB saw its role in the Dominican Republic as haphazardly skimming talent until the 1990s (Klein, 2014). If MLB has an effect on attendance, the effect should grow after 1981.

The results of Equation 2 are shown in Table 1. Only boys ages 13 to 16 are included, since these are prime ages of recruitment and training for baseball prospects. Relative to 1981, a one standard deviation increase in the MLB exposure variable causes no decrease in school attendance in 2002; in 2010, a one standard deviation increase in the MLB exposure variable causes a decrease of 0.2 percentage points in the probability of attending school, but the difference is not statistically significant (see Column 1). Consistent with Section 4.1, the evidence does not suggest that MLB is negatively affecting Dominican boys' education: there is no change in school attendance

in provinces where ballplayers tend to come from relative to other provinces after MLB ramped up investment in the Dominican Republic.

### 4.3 Comparing boys to girls

A third of test of whether teenage boys' educational outcomes respond to MLB's entry compares boys to girls in a triple-differences model. Equation 1 is adjusted as follows:

$$Education_{pt} = \sum_{t \neq 1959-62} \gamma_t Pre-MLB_p \cdot Male_i \cdot \delta_t + \theta_p \cdot \delta_t + \theta_p \cdot Male_i + \delta_t \cdot Male_i + \varepsilon_{pt} \quad (3)$$

and Equation 2 can be adjusted as follows:

$$Attendance_{apt} = \sum_{t > 1981} \gamma_t Pre-MLB_p \cdot Male_i \cdot \delta_t + \theta_p \cdot \mu_a \cdot \delta_t + \theta_p \cdot Male_i + \mu_a \cdot \delta_t \cdot Male_i + \varepsilon_{apt} \quad (4)$$

where  $Male_i$  is an indicator variable that takes the value of 1 for boys and 0 for girls. Birth cohort-specific province fixed effects allow educational outcomes to evolve commonly across genders over time within a province.

Equations 3 and 4 are within-province models, testing whether boys' educational outcomes change—or, in this case, worsen—relative to girls over time in communities more exposed to MLB's entry. If MLB negatively affects boys' educational outcomes, we should expect to see that boys' outcomes worsen relative to girls after MLB's entry in provinces more exposed to the shock. This approach has the advantage that it allows outcomes across provinces to vary over time. The identifying assumption is that boys'

educational outcomes would change at the same rates as girls' within provinces in the absence of the MLB's entry conditional on sex-specific birth cohort fixed effects. That is, the model controls for general changes in sex-specific outcomes over time under the assumption that the relative changes in sex-specific outcomes are common across provinces.

The results for Equation 3 are shown in Figure 5. Only one pre-1959 coefficient estimate is statistically significant across the three outcomes, for primary school completion, but in general the graphs indicate that there are no differential pretrends. The coefficient estimates after the reference period are usually positive and, in some cases, significantly different from zero. However, the reference year is essentially arbitrary and takes an anomalously low value—that is, both the pre- and post-treatment coefficients are positive. The pattern is clear across all three graphs that there is no major change over time and, certainly, no significant decline at any time that would suggest that professional baseball has a negative effect on education. The results are robust to using the number of baseball players from 1978 to 2009 per capita as an alternative measure of exposure (see Appendix Figure A2).

The results for Equation 4 are shown in Table 1, Column 2. Relative to 1981, the effect of MLB exposure for males in 2002 and 2010 is statistically indistinguishable from zero. That is, there is no evidence that the school attendance of males in baseball communities worsened relative to their female counterparts as MLB ramped up investment in the Dominican Republic. The magnitudes of the coefficients are tiny: the larger point estimate, for 2010, indicates that a one standard deviation increase in pre-MLB baseball culture

decreases the probability of school attendance by 0.5 percentage points for boys ages 13 to 16. Once again, the evidence does not suggest that MLB negatively affects Dominican boys' education, and certainly not on the scale suggested by popular media.

#### **4.4 Robustness check: 2006 expansion of US visas**

Chon (2020) also finds no effect of MLB recruitment on Dominican boys' educational outcomes but exploits the expansion of visas to the US in 2006 to identify the change in school attendance between the 2002 and 2010 censuses. A null result from that identification strategy may not be informative because there is no clear change after 2006 in the trend of the number of Dominicans playing American professional baseball, as seen in Figure 1.3 of that study (reproduced here as Figure A5). It is not obvious that the increase in the number of visas would change boys' perceived returns to education.

However, according to Klein (2014), the supply of H2B visas was limited before 2006 such that baseball teams had to be selective in sending minor leaguers to the United States, resulting in a backlog of players left in the Dominican academies. The Compete Act of 2006 expanded the supply of H2B visas for minor league baseball players, among other workers, and relieved the backlog. It is possible that this change affected boy' perceived returns to education, knowing that the chances of playing in the United States improved.

As a robustness check, we follow Chon (2020) in testing whether educational outcomes changed between 2002 and 2010 in response to the 2006 US visa expansion. The difference between our work and the previous study is

that Chon defines treatment as binary and only includes municipalities close to MLB academies in the treatment group. This classification is problematic because there are some areas, such as Peravia and Monte Cristi, that produce professional ballplayers at a high rate but fall in the control group. In this analysis, since the policy change occurs in 2006, we tweak the exposure variable to include all ballplayers who debut in American professional baseball between 1978 and 2006 and divide it by the population of the province in 2002.

Additionally, following Chon, instead of comparing boys to girls as we do elsewhere, we compare boys age 14 to 17 (treated) to boys age 18 to 21 (control). When the US visa expansion took effect in 2007, boys aged 11 to 14 were young enough to respond to the policy change and prepare for MLB academy tryouts, whereas boys slightly older already would have needed to prepare for years. Boys aged 11 to 14 would be 14 to 17 years old in 2010.

Table 2 displays results for regressions reevaluating the effect of the 2006 US visa expansion on boys' education, approximating the analysis in Chon (2020). If the visa expansion worsened educational outcomes, boys age 14 to 17 in the census should fare relatively worse than boys 18 to 21 in municipalities with stronger preexisting baseball cultures after the policy change. In reality, there is no evidence from the triple-differences model to suggest that their outcomes worsened, as the differences are all small and statistically insignificant.

## 5 Discussion and conclusion

This paper studies changes in educational outcomes across provinces before and after MLB's entry into the Dominican Republic and finds no evidence that professional baseball worsens outcomes. The result is surprising in light of abundant statements made in the popular press and legal journals attributing poor educational outcomes to recruitment for professional baseball. It is also not difficult to imagine that young boys in a developing country would take their chances at making millions of dollars, especially when seeing so many of their countrymen playing professionally on television. Yet, the educational outcomes of boys in communities more exposed to MLB's entry do not worsen relative to boys in less affected communities in response to MLB recruiting, and boys' outcomes likewise do not worsen compared to girls in those communities. Poor educational outcomes for boys in the Dominican Republic are not the result of MLB recruiting.

A simple explanation for the null result is that poor educational outcomes are a reflection of an underperforming educational system rather than of baseball. Educational outcomes in the Dominican Republic over the period studied are generally poor, not only for baseball players. Many ballplayers likely would not have been in school anyway; of all Dominican males born in the early 1970s, around half completed 8th grade and only a quarter finished 12th grade. As Klein (2014) notes, low education levels among ballplayers does not mean that they are less educated than the population at large. Of the 30 boys that Klein (1991) followed in 1987-89, six (or 20%) had a high school diploma, which is not far from the national average of about

27% according to IPUMS census data, particularly for a small sample. More recently, Klein (2014) also claims that the MLB Commissioner’s Dominican Office informed him that ballplayers slightly exceeded the national average for high school completion.<sup>16</sup> In general, Dominicans undervalue education, as the perceived returns to secondary education are extremely low despite measured returns (Jensen, 2010), and baseball prospects perceive a career path through education as complex and uncertain for them (ENTRENA et al., 2022).

Another explanation for the null result may be that dropping out of school may not be as common among baseball prospects as previously thought. According to ENTRENA et al. (2022), 96% of those surveyed still attended school, although mostly in non-traditional settings, and just 7% did not expect to attend school the following year. However, such attachment to schooling may be the result of recent efforts by MLB and partners to emphasize education and may not apply to earlier decades. Nonetheless, only 24% of respondents practiced baseball more than 20 hours per week, leaving ample time for education, and nearly three quarters expected to resume studies full-time if not signed to a professional baseball contract. The median prospect practices baseball 10 to 15 hours per week, which is comparable to the mean number of hours (11.6) that American high school athletes expect to participate in their primary sport in season (Gagliardi et al., 2020).

Lastly, a related explanation for the null result is that the total number of boys seriously pursuing professional baseball may not be as large as speculated.

---

<sup>16</sup>Notably, although many prospects come from low-income backgrounds, 84.3% of the surveyed prospects have access to water within their home, which suggests that the prospects do not belong to the lowest income levels of the country. Klein (1991, p. 69) reports that a “fair number” of rookies are the middle-class sons of journalists, clerks, and teachers.

Many of the supposed prospects may dream of a career in the MLB without giving up on other pursuits, no different than young athletes across the world, such that those who dropout for baseball and who otherwise would have remained in school represent only a tiny fraction of players. In this scenario, we may not have the power to detect an effect, but the effect would be small enough to be unimportant from a policy perspective and would not alter the conclusion that baseball is not causing an educational crisis.

Studying baseball and education in the Dominican Republic contributes to our understanding of the relationship between education and employment opportunities. Baseball is defined by high risk and high reward, like other careers in sports and entertainment and unlike careers previously studied. The Dominican Republic is an ideal location for studying the effect of such careers on education because of baseball's prevalence and the relative lack of other very lucrative career options. The absence of evidence that boys' educational outcomes respond to MLB recruiting suggests that careers defined by high risk and high reward are unlikely to shape educational decisions.

Figure 3: Dominican MLB and MiLB players over time, by province of birth (per 100,000 population)

Sources: Baseball-Reference.com and The Baseball Cube

Figure 4: The effect of MLB on boys' education

(a) Primary school completion (0/1)

(b) Secondary school completion (0/1)

(c) Years of schooling

Notes: This figure is based on Equation 1. The dependent variable is shown above each panel. The x-axis depicts birth year. Coefficients correspond to the pre-MLB exposure variable interacted with birth year fixed effects. Men born from 1959 to 1962 are the reference group. Error bars are 95 percent confidence intervals.

Figure 5: Comparing boys to girls: The effect of MLB on boys' education

(a) Primary school completion (0/1)

(b) Secondary school completion (0/1)

(c) Years of schooling

Notes: This figure is based on Equation 3. The dependent variable is shown above each panel. The x-axis depicts birth year. Coefficients correspond to the pre-MLB exposure variable interacted with birth year fixed effects and a male indicator variable. Men born from 1959 to 1962 are the reference group. Error bars are 95 percent confidence intervals.

## B Tables

Table 1: The effect of MLB on boys' school attendance, 1981-2010

Dependent variable: school attendance	(1)	(2)	(3)	(4)
$Pre-MLB_p \times \delta_{2002}$	0.002	-0.004		
× _____	(0.005)	(0.009)		
$Pre-MLB_p \times \delta_{2010}$	-0.002	-0.005		
× _____	(0.005)	(0.009)		
$MLB\ 1978-2009_p \times \delta_{2002}$			0.001	0.000
× _____			(0.005)	(0.009)
$MLB\ 1978-2009_p \times \delta_{2010}$			-0.002	-0.000
× _____			(0.005)	(0.009)
3rd interaction	None	$Male_i$	None	$Male_i$
Sex	M	M/F	M	M/F
Observations	372	744	372	744

Notes: This table is based on Equations 2 and 4. Coefficients in the top two rows correspond to the pre-MLB exposure variable interacted with census year fixed effects. Coefficients in the bottom two rows correspond to to players debuting 1977- 2010 divided by the provincial population interacted with census year fixed effects. Census year 1981 is the reference group. Sample only includes ages 13 to 16. Standard errors are shown in parentheses. Significance levels are denoted by \* p <.10, \*\* p <.05, \*\*\* p <.01.

Table 2: Reconsidering the effect of the 2006 US visa expansion on boys' education

Dependent variable:	Years of school	Primary completion
	(1)	(2)
<i>Pre-2007 MLB<sub>p</sub></i> $\times \delta_{2010} \times \text{Age } 14-17_i$	0.06 (0.11)	0.002 (0.008)
Observations	496	496

Notes: This table is based on Equation 2. *Pre-2007 MLB<sub>p</sub>* is the per capita number of players debuting in American professional baseball from province  $p$  from 1978 to 2007, standardized to have a mean of 0 and a standard deviation of 1. Census year 1981 is excluded. Census year 2002 is the reference year. Following Chon (2020), boys ages 14-17 are the treatment group and boys ages 18-21 are the control group. Significance levels are denoted by \*  $p < .10$ , \*\*  $p < .05$ , \*\*\*  $p < .01$ .

## C Additional Figures

Figure A1: The effect of MLB on boys' education (MLB 1977-2010 exposure variable)

(a) Primary school completion (0/1)

(b) Secondary school completion (0/1)

(c) Years of schooling

Notes: This figure is based on Equation 1. The dependent variable is shown above each panel. The x-axis depicts birth year. Coefficients correspond to players debuting 1977-2010 divided by the provincial population interacted with birth year fixed effects. Men born from 1959 to 1962 are the reference group.

Figure A2: Comparing boys to girls: The effect of MLB on boys' education (MLB 1977-2010 exposure variable)

(a) Primary school completion (0/1)

(b) Secondary school completion (0/1)

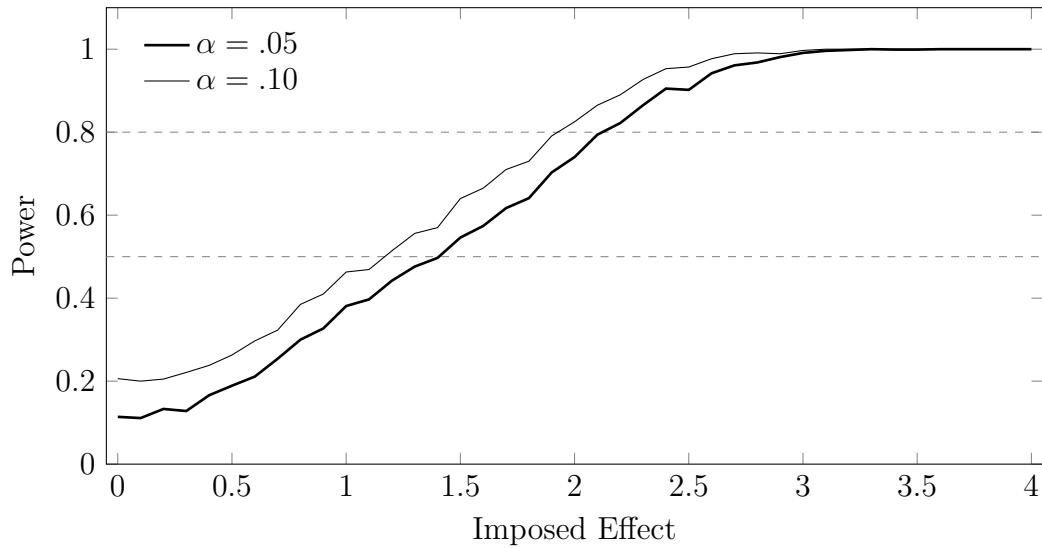

(c) Years of schooling

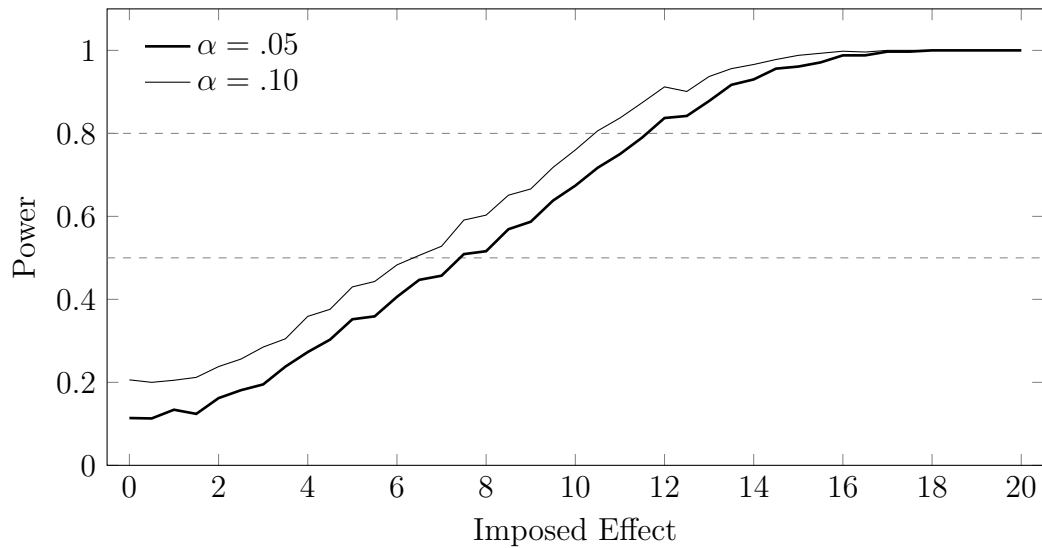

Notes: This figure is based on Equation 3. The dependent variable is shown above each panel. The x-axis depicts birth year. Coefficients correspond to players debuting 1977-2010 divided by the provincial population interacted with birth year fixed effects and a male indicator variable. Men born between 1959 and 1962 are the reference group.

Figure A3: Power simulation results (Primary school completion (0/1))

(a) Imposed effect: percentage points per standard deviation change in *Pre-MLB*

(b) Imposed effect: percentage points per change in *Pre-MLB* from least to most affected province

Notes: Each line represents results from 1000 simulations. Each simulation reruns Equation 1 with primary school completion as the dependent variable for girls only. Exposure to MLB recruiting is randomly reassigned to provinces and an effect is then imposed on provinces corresponding to the assigned exposure. Statistical significance is measured for an average of coefficients for the last 24 birth years.

Figure A4: Validity check for power analysis

Imposed Effect (percentage points per change from least to most affected province)

Notes: Each dot represents results from 1000 simulations. Each simulation reruns Equation 1 with primary school completion as the dependent variable for girls only. Exposure to MLB recruiting is randomly reassigned to provinces and an effect is then imposed on provinces corresponding to the assigned exposure. The estimated effect is an average of coefficients for the last 24 birth years.
